## Description

In accordance with Resolutions M 28-11 of the 28th SC 2 Plenary meeting, Waterloo, Ontario, Canada, 2023-06-19 and 23, this document is circulated for a CD consultation. The consultation period is 12 -week at the reuqest of the Project Editor though the Resolution says " 8 -week CD consultation".

Please submit comments via the ISO electronic balloting system by the due date indicated.

## Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and nongovernmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see www.iso.org/patents).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see www.iso.org/iso/foreword.html.

The committee responsible for this document is ISO/IEC JTC 1, Information technology, SC 2, Coded character sets.

This seventh edition of ISO/IEC 14651 cancels and replaces the sixth edition (ISO/IEC 14651:2020), which has been technically revised.

This edition includes the following significant changes with respect to the previous edition:

- The Common Template Tables are now referenced externally, removing the need for frequent update to this Standard.

## Introduction

This document provides a method, applicable around the world, for ordering text data, and references Common Template Tables which, when tailored, can meet a given language's ordering requirements while retaining reasonable ordering for other scripts.

Common Template Tables require some tailoring in different local environments. Conformance to this document requires that all deviations from these templates, called "deltas", be declared to document resultant discrepancies.

This document describes a method to order text data independently of context.
ISO/IEC TR 30112 has specifications for ordering that informatively complement the specifications in this document and indicates where additional information can be sought on ordering keywords defined in this document.

# Information technology - International string ordering and comparison - Method for comparing character strings and description of the common template tailorable ordering 

## 1 Scope

This document

- defines a reference comparison method. This method is applicable to two or more character strings to determine their collating order in a sorted list. The method can be applied to strings containing characters from the full repertoire of ISO/IEC 10646. This method is also applicable to subsets of that repertoire to produce ordering results valid (after tailoring) for a given set of languages for each script. This method uses collation tables derived either from the Common Template Tables (CTT) referenced by this document or from one of their tailoring. The format of the Common Template Table is described using the Backus-Naur Form (BNF). The format is used normatively within this document.
- defines syntax elements to tailor these Common Template Tables used by the reference comparison method.
- defines requirements for a declaration of the differences (delta) between a collation table and a given Common Template Table including the tailoring elements.
These Common Template Tables describe an order for all characters encoded in the current and past ISO/IEC 10646 editions, including amendments. They allow for a specification of a fully deterministic ordering. These tables enable the specification of a string ordering adapted to local ordering rules, without requiring an implementer to have knowledge of all the different scripts already encoded in the Universal Coded Character Set (UCS).

All these Common Template Tables have reference names which are related to a particular stage of development of the ISO/IEC 10646 Universal coded character set or a particular version of the Unicode Standard. These names and their relationship with ISO/IEC 10646 or the Unicode Standard repertoire are specified by an externally referenced document: Unicode Technical Standard, UTS \#10, Unicode Collation Algorithm.

## This document does not

- mandate a specific comparison method; any equivalent method giving the same results is acceptable.
- mandate a specific format for describing or tailoring tables in a given implementation.
- mandate specific symbols to be used by implementations.
- mandate any specific internal format for intermediate keys used when comparing, nor for the table used. The use of numeric keys is not mandated either.
- mandate a context-dependent ordering.
- mandate any particular preparation of character strings prior to comparison.

NOTE 1 - It is normally necessary to do preparation of character strings prior to comparison even if it is not prescribed by this document (see Annex C).
NOTE 2 - Annex D describes problems that gave way to this International Standard with their anticipated solutions.

## 2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

https://www.unicode.org/reports/tr10/

## 3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.
ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- IEC Electropedia: available at https://www.electropedia.org/
- ISO Online browsing platform: available at https://www.iso.org/obp

## 3.1

## character string

sequence of characters considered as a single object
Note 1 to entry - A character string to be ordered does not normally include the characters that delimit it, as for example an "end of line" control character in a text file to be sorted.

## 3.2

## Collating symbol

symbol (3.12) used to specify weights assigned to a collating element (3.4)

```
3.3
collation table
weighting table
mapping from collating elements (3.4) to weighting elements (3.14)
```

## 3.4 <br> collating element

sequence of one or more characters that are considered a single entity for ordering (3.7)

## 3.5

## delta

list of the differences between a given collation table (3.3) and another one
Note 1 to entry - The given collation table, together with a given delta, forms a new collation table.
Note 2 to entry - Unless otherwise specified in this document, the term "delta" always refers to differences from a Common Template Table as defined in this document.

## 3.6

Level
Collation level
sequence number for a subkey (3.11) in the series of subkeys forming a key

## 3.7 <br> ordering <br> collation

process by which, given two strings, it is determined whether the first one is less than, equal to, or greater than the second one

```
3.8
ordering key
sequence of subkeys (3.11) used to determine an order
```

```
3.9
preparation
collation preparation
process in which given character strings (3.1) are mapped to (other) character strings before the calculation of the ordering key (3.8) for each of the strings
```

### 3.10

```
reference comparison method
method for establishing an order between two ordering keys (3.8)
```

Note 1 to entry - See Clause 6.

### 3.11

subkey
sequence of weights computed for a character string (3.1)

### 3.12

symbol
collating element (3.4)
3.13
weight
collation weight
positive integer value, used in subkeys (3.11), reflecting the relative order of collating elements (3.4)

### 3.14

## weighting element

list of a given number of weights sequentially ordered by level

## 4 Symbols and conventions

Following ISO/IEC 10646, characters are referenced as UX where X stands for a series of one to eight hexadecimal digits (where all the letters in the hexadecimal string are in upper case) and refers to the value of that character in ISO/IEC 10646. This convention is used throughout this document.

Any use of the term 'The Common Template Table' in this document is applicable to all instances of Common Template Tables referenced in Annex A. The term can also be abbreviated as 'CTT'.

In the Common Template Table, arbitrary symbols representing weights are used according to the BNF notation description in 6.3.1.

## 5 Conformance

A process is conformant to this document if it produces results identical to those that result from the application of the specifications given in 6.2 to 6.5 .

A declaration of conformity to this document shall be accompanied by a statement, either directly or by reference, of the following:

- the name of the Common Template Table used by the process;
- the number of levels that the process supports; this number shall be at least three;
- whether the process supports the forward position processing parameter;
- whether the process supports the backward processing parameter and at which level;
- the tailoring delta described in 6.4 and how many levels are defined in the delta;
- if a preparation process is used, the method used shall be declared.

It is the responsibility of implementers to show how their delta declaration is related to the table syntax described in 6.3, and how the comparison method they use, if different from the one mentioned in Clause 6, can be considered as giving the same results as those prescribed by the method specified in Clause 6. The use of a preparation process is optional, and its details are not specified in this document.

It is strongly recommended that processes present available tailoring options to users.

## 6 String comparison

### 6.1 Preparation of character strings prior to comparison

It can be necessary to transform character strings before the reference comparison method is applied to them. Although not part of the Scope of this document, preparation can be an important part of the ordering process. See Annex C for some examples of preparation.

Characters of the input string shall be encoded according to ISO/IEC 10646 (UCS) or a mapping to ISO/IEC 10646 shall be provided if another encoding scheme is used.

Therefore, it can be an important part of the preparation phase to map characters from a non-UCS encoding scheme to the UCS for input to the comparison method. This task can, amongst other things, encompass the correct handling of escape sequences in the originating encoding scheme, the mapping of characters without an allocated UCS codepoint to an application-defined codepoint in the private zone area and change the sequence of characters in strings that are not stored in logical order. For example, for visual order Arabic code sets, input strings shall be put into logical order; and for some bibliographic code sets, strings with combining accents stored before their respective base character require that the combining accents be put after their base character. The resulting string sequence may then have to be remapped into its original encoding scheme.

The Common Template Table is designed so that combining sequences and corresponding single characters (precomposed) will have precisely the same ordering. To avoid inadvertently breaking this invariant (and in the process breaking Unicode conformance), tailoring should reorder combining sequences when corresponding precomposed characters are reordered. For example, if Ä is reordered after Z, then the sequence $<A>+<$ combining diaeresis> should also be reordered. To avoid exposing encoding differences that can be invisible to the end-user, it is recommended that strings be normalized according to Unicode normalization form NFD to achieve this equivalence (see [12]).

Escape sequences and control characters constitute very sensitive data to interpret, and it is highly recommended that preparation should filter out or transform these sequences.

NOTE - Since the reference method is a logical statement for the mechanism for string comparison, it does not preclude an implementation from using a non-UCS character encoding only, as long as it produces results as if it were using the reference comparison method.

### 6.2 Key building and comparison

### 6.2.1 Preliminary considerations

### 6.2.1.1 Assumptions

The collation table is a mapping from collating elements to weighting elements. In each weighting element, four levels are described in the Common Template Table. This number of levels can be extended or reduced, but cannot be less than 3 , in tailoring.

NOTE - In the Common Template Table, levels generally have the following characteristics, although this purpose is not absolute.
Level 1: This level generally corresponds to the set of common letters of the alphabets for that script, if the script is alphabetic, and to the set of common characters of the script if the script is ideographic or syllabic.
Level 2: This level generally corresponds to diacritical marks affecting each basic character of the script. For some languages, letters with diacritics are always considered an integral part of the basic letters of the alphabet and are not considered at this second level, but rather at the first. For example, in Spanish, N TILDE is considered a basic letter of the Latin script. Therefore, tailoring for Spanish will change the definition of N TILDE from "the weight of an N in the first level and the weight of a TILDE in the second level" to "the weight of an N TILDE (placed after N and before 0 ) in the first level, and indication of the absence of a diacritic in the second level". For some characters, variant letter shapes are also dealt with on level 2 . An example of this is $ß$, the LATIN SMALL LETTER SHARP S, which is treated as equivalent to ss on level 1, but traditionally distinguished from it on level 2.
Level 3: This level generally corresponds to case distinctions (upper and lower case) or to distinctions based on variant letter shapes (like the distinction between Hiragana and Katakana).
Level 4: This level generally corresponds to weighting differences that are less significant than those at the other levels. Often the last level (level 4 in the Common Template Table) is intended to specify additional weighting for "special" characters, i.e. characters normally not part of the spelling of words of a language (such as dingbats, punctuation, etc.), sometimes called "ignorable" characters in the context of computerized ordering.

### 6.2.1.2 Processing properties

A given tailored table has specific scanning and ordering properties. These properties can have been changed by the tailoring.

A scanning direction (forward or backward) for each level is used to indicate how to process the string. The scanning direction is a global property of each level defined in the tailored table.

If the last level is greater than three, there is an optional property of this level of comparison called "position" option: when active, a comparison on the numeric position of each "ignorable" character in the two strings is effected, before comparing their weights. In other words, for two strings equivalent at all levels except the last one, the string having an ignorable character in the lowest position comes before the other one. In case corresponding ignorable characters are at the same position, then their weights are considered, until a difference is found. Support for this kind of processing is optional and is not necessary to claim conformance to this document.

NOTE - The scanning direction (forward or backward) is not normally related to the natural writing direction of scripts. The scanning direction applies to the logical sequence of the coded character string.
According to ISO/IEC 10646, for scripts written right to left, such as Arabic, the first characters in the logical sequence correspond to the rightmost characters in their natural presentation sequence. Conversely, for the Latin script, written left to right, the first characters in the logical sequence correspond to the leftmost characters in their natural presentation sequence.

Scanning forward starts with the lowest position in the logical sequence, while scanning backward starts from the highest position, independently of the presentation sequence. The scanning direction for ordering purposes is a global property of each level described in the table.

In ISO/IEC 10646, the Arabic script is artificially separated into two pseudo-scripts: 1) the logical, intrinsic Arabic, coded independently of contextual shapes, and 2) the Arabic presentation forms. Both allow the complete coding of Arabic, but intrinsic Arabic is normally preferred for better processing, while presenta-tion-form Arabic is preferred by some presentation-oriented applications. ISO/IEC 10646 does not prescribe that the presentation forms be stored in any specific order, and in some implementations, the storage order for the latter is the reverse of the storage order used for intrinsic Arabic. It is therefore advisable that the preparation phase be used to make sure that Arabic presentation forms and other Arabic characters be fed to the comparison method in logical order.

A tailored sort table can be separated into sections for ease of tailoring. Each section is then assigned a name consistent with the specification in 6.3.1. One of the tailoring possibilities is to assign a given order to each section and to change the relative order of an entire section relative to other sections.

### 6.2.2 Reference ordering key formation

### 6.2.2.1 General

When two strings are to be compared to determine their relative order, the two strings are first parsed into a sequence of collating elements taking into account the multi-character "collating-element" statements declared and used in a tailored table (if the syntax of 6.3.2 is used). For the syntax used for expressing the Common Template Table, the name of a collating element consisting of a single character, is formed by the UCS value of the character, expressed as a hexadecimal string, prefixed with "U". For multi-character collating elements, the name and association to characters can be found via the collating elements declarations.

> NOTE - Collating elements with more characters have preference over shorter ones. As an example, if a multicharacter collating element is defined for "abc" and another one is defined for "ab" or for "bc", then if "abc" is encountered, the collating element for "abc" will apply and not the one for "ab" or "bc".

Then, a sequence of $m$ intermediary subkeys is formed out of a character string, where $m$ is the number of levels described in a tailored collation weighting table.

Each ordering key is a sequence of subkeys. Each subkey is a list of numeric weights. A subkey is formed by successively appending the list of the weights assigned, at the level of the subkey, to each collating element of the string. The keyword "IGNORE" in the Common Template Table at the place of a sequence of collating symbols at a level indicates that the sequence of weights at that level for that collating element is an empty sequence of weights.

### 6.2.2.2 Weighting elements to be ignored

When forming a sort key, collating elements ignored at the first level or at the two first levels and that follow a collation element ignored at all levels but the last one, do not keep their weights as defined in the common template table (or a tailored table); each of these weights shall be zeroed (this means that "IGNORE" shall be assigned to each non-nil weight).

### 6.2.2.3 Implicit weights computing

If there is no entry in the tailored table for a character of the input string, then the character's weights are undefined. In this case, one shall compute an "implicit" primary weight consisting of a pair of 16bit words — call them "aaaa" and "bbbb" - and assume that lines like the following were added to the weighting table:

$$
\text { <UXXXX> "<R\{aaaa16\}><T\{bbbb } 16\}>" ;<\text { BASE>;<MIN>;<SFFFF> }
$$

NOTE $1-<$ SFFFF $>$ (at the last level) is the largest level 1 weight in the Common Template Table.
Distinctions are needed among characters with no entry in the weighting table, and implicit primary weights are thus computed. A 'base weight' is assigned to these characters, and specific functions are used to derive the "aaaa" and "bbbb" values. These "base weight" values and functions are defined in the Unicode Technical Standard \#10 (see Clause 2) at https://www.unicode.org/reports/tr10/\#Values_For_Base_Table. The following shows examples for some of these "base weight" and functions for specific characters and how they are used to determine the "aaaa" and "bbbb" for a given code point cp:

```
EXAMPLES
CIK Unified Ideographs
base_weight = 0xFB40 for original CJK Unified Ideographs (URO)
base_weight = 0xFB80 for CJK Extension A through Extension G
aaaa =[base_weight + (cp >> 15)] ]16
bbbb = [(cp & 0x7FFF) | 0x8000] 16
Tangut Ideographs and Components
base_weight = 0xFB00
aaaa =[base_weight] }\mp@subsup{}{16}{
bbbb =[(cp-0x17000)| 0x8000] 16
Nüshu Characters
base_weight = 0xFB01
aaaa =[base_weight ]}\mp@subsup{}{16}{
bbbb = [(cp-0x1B170)| 0x8000] [16
Khitan Small Script Characters
base_weight = 0xFB02
aaaa = [base_weight] }\mp@subsup{}{16}{
bbbb =[(cp-0x18B00)| 0x8000] }\mp@subsup{}{16}{
```

Thus, the value of the code point is used to calculate the desired weights, by operating on individual bits. The two numbers, converted to four-character hexadecimal values, will then take the following form: "<Raaaa><Tbbbb>".

Decomposable characters are excluded from these computing, as they have an entry in the Common Template Table (with dual primary weights).

If a string contains ill-formed code unit sequences, two approaches show up: the sequence can be handled as if it were U+FFFD (REPLACEMENT CHARACTER), or each subsequence can be ignored. The same approaches can be adopted for any out-of-range values ( $\mathrm{cp}>10 \mathrm{FFFF}_{16}$ ).

NOTE 2 - When computed weights are used, characters without explicit mappings are sorted in code point order within each set they belong to and they sort properly with respect to the rest of the characters.

### 6.2.2.4 Subkeys formation

There are three ways of forming subkeys: subkeys formed using the "forward" processing parameter, subkeys formed using the "backward" processing parameter, and subkeys formed using the "forward,position" processing parameter. Subkeys that use the "position" option can only occur at the last level, and only if that level is greater than three. Support of the "position" option is not required for conformance. If the processing parameter "forward, position" is not supported, "forward, position" shall be interpreted as if the processing parameter had been "forward".

### 6.2.2.5 Formation of subkeys for the first three levels

With the "forward" or "forward,position" processing parameter, during (forward) scanning of each collating element of the input character string, one or more weights are obtained. These weights are obtained by matching the collating element in the given tailored collation weighting table, obtaining the list of weights assigned to the collating element at the particular level. The obtained weight list is appended to the end of the subkey.

Subkeys, at a particular level, formed with the "backward" level processing parameter are built by forming a subkey as with the "forward" parameter, then reversing that subkey weight by weight.

### 6.2.2.6 Formation of the level 4 subkey

At the last level, the subkey is built as described in the preceding paragraph. However, once the ordering key is completely formed (when the end of the string is reached), there are two possible approaches:
a) With the "forward" processing parameter: all the <SFFFF> symbols are backed out of the subkey;
b) With the "forward, position" processing parameter: any trailing sequence of <SFFFF> symbol(s) shall be removed from the subkey (leaving intact the remaining part of the subkey).

### 6.2.3 Reference comparison method for ordering character strings

The reference comparison method for ordering two given character strings (after collation preparation, which is not part of the reference comparison method itself) is to compare ordering keys generated by the reference key formation method described in 6.2.2.

- Begin by building an ordering key, using a given tailored collation weighting table, for each of the two given character strings being compared.
- Then compare the resulting keys according to the key ordering definition presented in 6.2.4. Keys can be compared either up to a given level, or up to the last level of the given tailored collation weighting table.

NOTE - The comparison can be made while generating the ordering keys for two strings to be compared, stopping the key generation when the order of the strings can be determined. Such a technique is sometimes termed lazy evaluation, and some systems support it by default. This avoids generating the full ordering key when an ordering difference is found early in the keys. When a bigger set of strings are to be ordered, one can generate the ordering keys, for example, and store each key or an initial segment of each, before comparing the keys.

### 6.2.4 Key ordering definition

Weights for different levels should not be compared, which implies that subkeys at different levels should not be compared, nor should keys generated from different tailored tables be compared.

NOTE 1 - This allows implementations to assign weightings at each level independently of the other levels, and independently of other tailoring.
$m$ is the maximal level of a given tailored table. Recall that a key is a list, of length $m$, of subkeys; a subkey is a list of weights; and a weight is a positive integer. Other notations used below are the following:

- $L_{z}$ is the length of the subkey $z$, i.e., the number of weights in the subkey;
- $z_{w t(a)}$, where $1 \leqslant a \leqslant L_{z}$, is the weight at index position $a$ (an integer $>0$ ) of the subkey $z$;
- $u_{s k(b)}$, where $1 \leqslant b \leqslant m$, is the subkey at level $b$ (an integer $>0$ ) of the key $u$.

The orderings of weights, subkeys, and ordering keys (up to a given level, or up to the last level) are total order relations, defined for a given tailored collation table as follows.
a) Weights are positive integers (in the reference method) and are compared as such for the purposes of collation.
b) A subkey v is less than a subkey $w$ (written $v<w$ ) if and only if there exists an integer, $i$, where $1 \leqslant i \leqslant L v+1$ and $i \leqslant L w$, such that

- $\quad i=1$ and $v_{w t} t_{(i)}<w_{w t}(i)$, or
- for all integers, $j$, where $1 \leqslant j<i$, the equality $v_{w t(j)}=w_{w t(j)}$ holds, and either
- $\quad i \leqslant L_{v}$ and $v_{w t(i)}<w_{w t}(i)$, or
- $\quad i=L v+1$ and $0<w_{w t}(i)$.

A subkey $v$ is greater than a subkey $w$ (written $v>w$ ) if and only if $w$ is less than $v$. A subkey $v$ is equal to a subkey $w$ (written $v=w$ ) if and only if neither $v$ is less than $w$, nor $w$ is less than $v$.
c) An ordering key $x$ is less than an ordering key $y$ at level $s$ (written $x<_{s} y$ ) if and only if there exists an integer $i$, where $1 \leqslant i \leqslant s$ and $i \leqslant m$, such that

- $\quad i=1$ and $x_{s k(i)}<y_{s k(i)}$, or
- for all integers $j$, where $1 \leqslant j<i$, the equality $x_{s k(j)}=y_{s k(j)}$ holds, and $x_{s k(i)}<y_{s k(i)}$.

An ordering key x is greater than an ordering key $y$ at level $s$ (written $x>_{s} y$ ) if and only if $y$ is less than $x$ at level $s$. An ordering key $x$ is equal to an ordering key $y$ at level $s$ (written $x=s y$ ) if and only if neither $x$ is less than $y$ at level $s$, nor $y$ is less than $x$ at level $s$.
d) For ordering keys, $<,>$, and $=$ are defined as $<_{m},>_{m}$, and $=_{m}$ respectively.

NOTE 2 - For ordering keys, $x<_{t} y$ implies $x<_{t+1} y, x>_{t} y$ implies $x>_{t+1} y, x=_{t} y$ implies $x=_{t-1} y, x<0 y$ is false, $x>_{0} y$ is false, and $x=o y$ is true. Above level m , for a given tailored table, there are no further ordering distinctions. Note that this definition implies that if two ordering keys are in the 'less than' relationship at level 1 , they will also be in the 'less than' relationship at levels $2,3,4$, etc. In general, whenever two ordering keys are less than at a given level, they will also automatically be less than at all subsequent, higher levels. Conversely, if two ordering keys are equal at a given level, they will also automatically be equal at all preceding, lower levels.
NOTE 3 - The decomposition of character string into ordering keys of different levels of comparison from the most significant to the least significant also facilitates fuzzy searches and searches for equivalences. Annex E documents this kind of comparison.

### 6.3 Common Template Table: Formation and interpretation

### 6.3.1 General

This subclause specifies the following:

- the syntax used to form the Common Template Tables referenced in Annex A or a tailored table based upon one of the Common Template Tables referenced in Annex A;
- conditions of well-formedness of a table using this syntax;
- interpretation of tailoring statements in deltas for tables formed using this syntax;
- evaluation from symbols to weights of tailored tables formed using this syntax;
- conditions for considering two tables as equivalent;
- conditions for considering comparison results as equivalent.

### 6.3.2 BNF syntax rules for the Common Template Tables in Annex A

### 6.3.2.1 General

Definitions between <angle brackets> make use of terms not defined in this BNF syntax and assume general English usage.

Other conventions:

-     * indicates 0 or more repetitions of a token or a group of tokens;
-     + indicates 1 or more repetitions of a token or a group of tokens;
- ? indicates optional occurrence of a token or a group of tokens ( 0 or 1 occurrences);
- parentheses are used to group tokens;
- production rules are terminated by a semicolon.

Define collation tables as sequences of lines:

```
weight_table = common_template_table | tailored_table ;
common_template_table =
    simple_line+ ;
tailored_table = table_line+ ;
```

Define the line types:

```
simple_line = (symbol_definition | collating_element |
    weight_assignment | order_end)?
    line_completion ;
table_line = simple_line | tailoring_line ;
tailoring_line = (reorder_after | order_start | reorder_end |
    section_definition | reorder_section_after)
    line_completion ;
```

Define the basic syntax for collation weighting:

```
symbol_definition =
    'collating-symbol' space+ symbol_element ;
symbol_element = symbol | symbol_range ;
symbol_range = symbol '..' symbōl ;
symbol = simple_symbol | ucs_symbol ;
ucs_symbol = ('<U'' one_to_eight_digit_hex_string '>') |
    ('<U-' one_to_eight_digit_hex_string '>') ;
simple_symbol = '<' identi午ie\overline{r '>' ;}
collatíng_element =
        'collating-element' space+ symbol space+
    'from' space+ quoted_symbol_sequence ;
quoted_symbol_sequence =
        '"' simple_weight+ '"' ;
weight_assignment =
        simple_weight | symbol_weight ;
simple_weight = symbol_element | 'UNDEFINED' ;
symbol_weight = symbol_element space+ weight_list ;
weight_list = level E
level_
symbol_group = symbol_element | quoted_symbol_sequence ;
order_end = 'order_end' ;
```

Define the tailoring syntax:

```
reorder_after = 'reorder-after' space+ target_symbol ;
target_\overline{symbol = symbol ;}
order_start = 'order_start' space+ multiple_level_direction ;
multi\overline{ple_level_direction =}
        (direction semicolon)* direction (',position')? ;
direction = 'forward' | 'backward' ;
reorder_end = 'reorder-end' ;
section_definition =
    section_definition_simple |
    section_definition_list ;
section_definition_simple =
    '\overline{section' space+ section_identifier ;}
section_identifier =
    identifier ;
section_definition_list =
        'section' space+ section_identifier space+
    symbol_list ;
symbol_list = symbol_element (semicolon symbol_element)* ;
reorder_section_after =
    'reorder-section-after' space+ section_identifier
    space+ target_symbol ;
```

Define low-level tokens used by the rest of the syntax:

```
identifier = (letter | digit) id_part* ;
id_part = letter | digit | '_'r' | ' '' ;
line_completion =
    space* comment? EOL ;
comment = comment_char character* ;
one_to_eight_digit_hex_string =
    hex_uppēr | hex_upper hex_upper |
    hex_upper hex_upper hex_upper |
    hex_upper hex_upper hex_upper hex_upper |
    hex_upper hex_upper hex_upper hex_upper hex_upper
    hex upper hex upper hex upper
    hex_upper hex_upper hex_upper |
    hex_upper hex_upper hex upper
    hex_upper hex_upper hex_upper hex_upper |hex_upper
    hex_upper hex_upper hex_upper
    hex_upper hex_upper hex_upper hex_upper ;
hex_numeric_string =
    hex upper+ ;
space = , ,- | <TAB> ;
semicolon = ';' ;
comment_char = '%' ;
digit =- '0' | '1' | '2' | '3' | '4' |
hex upper = digit | 'A' | 'B' | 'C' | 'D' | 'E' | 'F' ;
let̄ter = 'a' | 'b' | 'c' | 'd' | 'e' | 'f' | 'g' |
    'h' | 'i' | 'j' | 'k' | 'l' | 'm' | 'n'
    'o' | 'p' | 'q' | 'r' | 's' | 't' | 'u' |
    'v' | 'w' | '\mathbf{x' | ''y' | 'z' |}
    'A' | 'B' | 'C' | '酐 | 'E' | 'F' | 'G'
    'H' | 'I' | 'J' | 'K' | 'L' | 'M' | 'N'
    'O' | 'P' | 'Q' | '㐌' | 'S' | 'T' | 'U' |
EOL = <end-of-line in the text conventions in use> ;
character = <any member of the repertoire of the encoded
    character set in use, not including any
    characters used to delimit the end of lines> ;
```

### 6.3.2.2 Keyword usage

The usage of the following locale syntax keywords is as follows.

| collating-symbol |  |
| :--- | :--- |
| collating-element | Defines a collating symbol representing a weight. <br> Defines a collating element symbol representing a multi-character collating element. |
| order_start | Defines collation rules. This statement is (after reordering is done) followed by one or <br> more collation order statements, assigning multi-level collation weightings to collating <br> elements. A collating element is either a character or a defined substring. |
| order_end | Specifies the end of the collating order statements. |
| reorder-after | Redefines collating rules. Specifies after which collating symbol weighting the lines be- <br> tween the "reorder-after" and the next (or "reorder-end") are to be moved. This state- <br> ment is followed by one or more collation table lines. The result is to reassign collating <br> symbol's values or collating element's weightings. |
| reorder-end | Specifies the end of the "reorder-after" collating order statements. |
| section | Defines a section of the table. A section can be moved as a whole by "reorder-section- <br> after". |
| reorder-section-after | Redefines the order of sections. This statement is followed by a section symbol and a <br> target symbol. The result is to reassign collating symbol's values or collating element's <br> weightings. |

### 6.3.3 Well-formedness conditions

WF 1. Any simple_symbol occurring in a weight_list shall also occur in the initial symbol_element of a symbol_weight, or symbol_definition that occurs no later in the sequence of lines that constitute a weight_table.

All simple_symbols shall be "defined" before they are "used".
WF 2. No symbol that occurs in a symbol_definition in a weight_table that contains no tailoring_lines may occur in another symbol_definition in the same weight_table.

Duplication of collation weighting symbols is prohibited. This is true for the Common Template Table itself. It shall remain true for a tailored_table after all reordering of lines has been applied.

WF 3. All weight_lists in a tailored_table shall contain the same number of level_tokens. An empty level_token shall be interpreted as the collating_element itself.

A tailorable table shall be consistent in its use of levels throughout.
WF 4. A tailored_table shall contain exactly one order_start statement followed later by exactly one order_end statement. The order_start statement shall appear after the symbol_definition entries and before the symbol_weight entries after all reordering of lines has been applied.

WF 5. A multiple_level_direction in a tailored_table shall contain the same number of directions as the number of level_tokens of any weight_list in that tailored_table.

Any order_start shall have the same number of levels as is generally used in the table.
WF 6. If a level_token in a weight_list consists of a symbol_group, all successive level_tokens in that weight_list shall also consist of a symbol_group.

IGNORE shall not be used at a level after an explicit symbol for a weighting.
WF 7. Any section_identifier occurring in a reorder_section_after shall occur in a section_definition that occurs earlier in the sequence of table_lines that constitutes a tailored_table.

All section_identifiers shall be "defined" before they are "used".
WF 8. No two section_definitions in a tailored_table shall contain the same values in their section_identifiers.

Multiple definitions of sections are prohibited; section_identifiers shall be unique.
WF 9. Each reorder_after in a tailored_table shall be followed at a later point in that tailored table by a reorder_end or another reorder_after.

WF 10. If the section_identifier of a statement reorder_section_after corresponds to the section_identifier of a section_definition_list, then the target_symbol of that statement reorder_section_after shall not have the same value as any of the symbols of the section_definition_list.

A section shall not be reordered after a line which the section itself contains; recursive relocation of lines is prohibited.

WF 11. Any symbol_range shall contain two symbols which meet the following conditions. 1) Each of the two symbols shall contain a common prefix of length one. The prefix can be any letter except ' $U$ '. 2) The portions of identifier of each of the two symbols following the common prefix shall be a hex_numeric_string containing the same number of hexadecimal digits. 3) When interpreted as numeric values, the hex_numeric_string of the first symbol shall be less than the hex_numeric_string of the second symbol. One plus the positive integral difference between the hex_numeric_string of the second symbol, interpreted as a numeric value, and the hex_numeric_string of the first symbol, interpreted as a numeric value, constitutes the number of values of the symbol_range.

NOTE 1 - A well-formed symbol_range is of a form such as <S4E00>..<S9FFF>, where the common prefix is "S", and the rest of the identifier portion of each symbol is a hex_numeric_string.

WF 12. Any symbol_weight that contains more than one symbol_range shall contain only symbol_ranges that meet the following requirement. Each symbol_range following the first symbol_range shall have the same number of values in its range as that of the first symbol_range.

NOTE 2 - This condition guarantees that all expanded ranges will be well-formed, since for any one symbol_ weight, all of the range expansions will have the same number of values.:

### 6.3.4 Interpretation of tailored tables

I 1. A section consists of either 1) the list of simple_lines which contain a symbol_definition whose value is equal to any symbol contained in the symbol_list in a section_definition_list, or 2 ) the list of simple_lines following a section_definition_simple in a tailored_table.

NOTE 1 - A section is defined 1) by a specific symbol_list, or 2) by taking all the lines following the section_definition until another tailoring line such as an order_start, a reorder_section_after, another section_definition, or the end of the table is encountered.

I 2. A simple_line consisting of a symbol_definition containing a symbol_range is equivalent to a sequence of simple_lines, where each of those lines contain a symbol in place of the symbol_range. The symbol for each successive simple_line is generated by concatenating a hex_numeric_string to the common prefix of the symbol_range, in numeric order, starting with the hex value associated with the hex_numeric_string of the first symbol in the range, and ending with the hex value associated with the hex_numeric_string of the second symbol. The hex_numeric_string concatenated to the common prefixes shall contain the same number of digits as the hex_numeric_string of the first symbol. The number of simple_lines thus generated is equal to the number of symbols in the symbol_range.

NOTE 2 - A symbol_definition of the form "collating-symbol <S0301>.. $<$ S0303>" is equivalent to the three lines:

- collating-symbol <S0301>;
- collating-symbol <S0302>;
- collating-symbol <S0303>.

I 3. A simple_line consisting of a symbol_weight containing one or more symbol_ranges is equivalent to a sequence of simple_lines, where each symbol_range has been expanded into a sequence of symbols, as described in I 2 for symbol_definition.

NOTE 3 - A symbol_weight of the form "<U2000>..<U2002><S0301>..<S0303>;<BASE>;<MIN>;<SFFFF>" is equivalent to the three lines:

- <U2000><S0301>;<BASE>;<MIN>;<SFFFF>;
- <U2001><S0302>;<BASE >;<MIN>;<SFFFF>;
- <U2002><S0303>;<BASE >;<MIN>;<SFFFF>.

I 4a. A tailored_table containing a reorder_after is equivalent to the tailored_table where:
a) all table_lines that were ahead of the reorder_after and that contained weight_assignments whose initial symbol matches the initial symbol of any weight_assignment in the table_lines between the reorder_after and reorder_end have been removed,
b) the table_lines between that reorder_after and the first subsequent reorder_end to immediately follow the first table_line in the tailored_table containing a weight_assignment whose initial symbol is the same as the target_symbol in the reorder_after have been reordered, and
c) that reorder_after and that reorder_end have been removed.

Move the block of lines between the reorder_after and the reorder_end to follow the target_symbol, delete any prior lines that duplicate the symbol_definitions of the reordered lines, and remove the reorder_after and reorder_end themselves.

I 4b. When a tailored_table contains multiple groups of lines to be reordered, the table is interpreted by processing each reorder_after sequentially, starting from the first line of the table.

NOTE 4 - Subsequent line reordering can impact lines that themselves were reordered by prior reordering.

I 5. A tailored_table containing a reorder_section_after is equivalent to the tailored_table with the section associated with that reorder_section_after reordered (in the same relative order as the table_lines have in that section) to immediately follow the last table_line in the tailored_table containing a symbol_definition whose symbol is the same as the target_symbol in the reorder_section_after, and with that reorder_section_after removed.

I 6. A weight_table is said to be in normal form when it contains no reorder_afters nor reorder_section_afters.

NOTE 5 - A tailored_table can be put into normal form by the operations implied by I 4 and I 5 .

### 6.3.5 Evaluation of weight tables

E1. A weight_table in normal form is said to be evaluated when each weight_assignment in the weight_table is mapped to a positive integer value (a weight) such that those values increase monotonically by the order in which the weight_assignments occur in the weight_table.

NOTE 1 - The table_lines of the weight_table can first be mapped to the set of positive integers, by sequential order in the table. This mapping defines an ordered set of line numbers. The weight_assignments are then mapped to a set of positive integers (weights) that varies monotonically with the set of line numbers.

This does not restrict the starting number for the weight of the first weight_assignment (other than it shall be positive) nor does it require that the numbers for these weights be immediately consecutive.

E 2. An evaluated weight_table is said to be collating-element-weighted when each simple_symbol occurring in each weight_list in that evaluated weight_table has been mapped to the weight that corresponds to the weight_assignment that contains the same simple_symbol.

NOTE 2 - Each weight_list can be interpreted as containing either symbol's mapped to integral weight values or as instances of the string 'IGNORE', which denotes the empty sequence of weights. At this point, the mathematical injection of strings can be defined using the weight_table.
NOTE 3 - In a tailored table, the value of any hex_numeric_string associated with a symbol generally does not reflect the numeric weighting of the symbol.

### 6.3.6 Conditions for considering specific table equivalences

A weight_table TBL1 and a weight_table TBL2 are said to be equivalent at a particular level if any comparison of strings using those tables up to that level results in the same ordering.

When two tables are claimed to be equivalent, one shall always get the same results in forming keys for two strings based on TBL1 and comparing them than by forming keys based on TBL2 and comparing them.

### 6.3.7 Conditions for results tobe considered equivalent

An implementation of international string ordering is conformant with this document if, for any set of strings $S$ defined on a repertoire $R$, the implementation can duplicate the same comparisons as those resulting from comparison of the numbers from an injection constructed according to the rules of 6.2.3.

### 6.4 Declaration of a delta

Tailoring shall be based upon a Common Template Table referenced in Annex A. Tailoring can be accomplished using any syntax that is equivalent to the one described in this document. Examples of tailoring delta can be found in Annex B.

NOTE 1 - For example, ISO/IEC TR 30112, uses a compatible extension of the syntax used in this document for tailoring. A tailoring delta can also be expressed using the syntax of the Unicode collation algorithm (see Clause 2). It has also been demonstrated that a tailoring delta can also be expressed using an XML-conformant mark-up scheme.

Any declaration of conformance to this document shall be accompanied with a declaration of the differences between the collation weighting table and the selected Common Template Table. A delta shall contain the equivalent of the following:
a) at least one valid order_start entry described in 6.3.2; an unlimited number of sections containing an order_start entry and an order_end entry can be declared;
b) the number of levels used for comparison;
c) the list of symbol_definition weights (as defined in 6.3.2) added and the position of the symbol_definition entry after which each insertion is made;
d) the list of simple_line entries (as defined in 6.3.2) deleted or inserted, referencing the position of the simple_line entry in the Common Template Table after which the insertions are made.

It is recommended that a delta should not be bigger than necessary.
In cases where a process allows the end-user to tailor the table himself or herself, a statement of conformance shall indicate which of the four elements of the previous list are tailorable and which of those four elements are not tailorable. For those which are not tailorable, the delta between fixed elements and the Common Template Table shall be declared.

NOTE 2 - The declaration can use a different syntax from the one specified in 6.3 provided that the relationship with this syntax can be reasonably established. For example, the following declarations are valid:

- "Collate U00E5 after U00FE at the primary level;
- "Collate U00E4 after U00E5 at the primary level. ";
- "The primary alphabet order is modified so that in all cases $\mathrm{z}<\mathrm{p}<\mathrm{a}<\mathrm{a} "$.

Note that the letters å and ä are sorted after Icelandic letter thorn (b), itself already coming after all the variants of the letter z , i.e. å and ä have a weight value higher at level 1 than the one for b , which itself comes after the ones for all variants of z .

The above two informal expressions can reasonably be considered to be equivalent to the following more precise expression (which also gives weights at levels 2 and 3 and explicitly takes care of accented å's, accented ä's and the Ångström sign):
reorder-after $<$ S00FE $>\%$ Weight for THORN (after $z$; and unlike $z$, $b$ has no variants).
\% Declare new collation symbols (weight names):
collating-symbol <S00E5> \% for å
collating-symbol <S00E4> \% for ä
\% Declare new collating elements for the decompositions (substring names):
collating-element <U0061_030A> from "<U0061><U030A>" \% decomposition of å
collating-element <U0041_030A> from "<U0041><U030A>" \% decomposition of $\AA$
collating-element <U0061_0308> from "<U0061><U0308>"\% decomposition of ä
collating-element <U0041_0308> from "<U0041><U0308>" \% decomposition of Ä
\% Assign weights to the new collation symbols (after THORN):
<S00E5> \% for à
<S00E4> \% for ä
reorder-end
reorder-after <SFFFF> \% The only place where we can put the order_start line.
order_start forward;forward;forward;forward
\% Use the new weighted collation symbols and collating elements to tailor the collation rules:
\% The letter Å:
<U00E5> <S00E5>;<BASE>;<MIN>;<SFFFF> \% LATIN SMALL LETTER A WITH RING ABOVE
<U0061_030A> <S00E5>;<BASE>;<MIN>;<SFFFF> \% decomposition of å
<U00C5> <S00E5>;<BASE>;<CAP>;<SFFFF> \% LATIN CAPITAL LETTER A WITH RING ABOVE
<U0041_030A> <S00E5>; <BASE>; <CAP>; <SFFFF> \% decomposition of $\AA$
<U212B> <S00E5>;<BASE>;<CAP>;<SFFFF> \% ANGSTROM SIGN (the letter Å really)
<U01FB> <S00E5>;"<BASE><AIGUT>";"<MIN><MIN>";"<SFFFF><SFFFF>"

```
% LATIN SMALL LETTER A WITH RING ABOVE AND ACUTE
<U01FA><S00E5>;"<BASE><AIGUT>";"<CAP><MIN>";"<SFFFF><SFFFF>"
% LATIN CAPITAL LETTER A WITH RING ABOVE AND ACUTE
% The letter Ä:
<U00E4><S00E4>;<BASE>;<MIN>;<SFFFF> % LATIN SMALL LETTTER A WITH DIAERESIS
<U0061_0308><S00E4>;<BASE>;<MIN>;<SFFFF> % decomposition of ä
<U00C4> <S00E4>;<BASE>;<CAP>;<SFFFF> % LATIN CAPITAL LETTER A WITH DIAERESIS
<U0041_0308><S00E4>;<BASE>;<CAP>;<SFFFF> % decomposition of Ä
<U01DF> <S00E4>;"<BASE><MACRO>";"<MIN><MIN>";"<SFFFF><SFFFF>"
% LATIN SMALL LETTER A WITH DIAERESIS AND MACRON
<U01DE> <S00E4>;"<BASE><MACRO>";"<CAP><MIN>";"<SFFFF><SFFFF>"
% LATIN CAPITAL LETTER A WITH DIAERESIS AND MACRON
reorder-end
```

### 6.5 Names of the Common Template Tables and name declaration

Prior to ISO/IEC 10646:2020 6th Edition Amendment 2, the names of the Common Template Tables used the following syntax: "ISO 14561_xxxx_TABLE1" where xxxx denoted the year. Names were created for the years 2000, 2002, 2003, 2005, 2006, 2008, 2010, 2012, 2014, 2015, 2016, 2017, and 2020. Starting with ISO/IEC 10646:2020 $6^{\text {th }}$ Edition Amendment 2, the names of Common Template Tables use a syntax referring to the synchronized Unicode Version. The CTT names are specified by the Unicode Collation Algorithm (see Clause 2) at https://www.unicode.org/reports/tr10/\#Synch_14651_Table.

EXAMPLE: For ISO/IEC 10646:2020 6 th Edition Amendment 2, the CTT name is "CTT_V16_0'
NOTE - Annex A contains linked references to all existing Common Template Tables prior to ISO/IEC 10646:2020 6th Edition Amendment 2. It also references all new Common Template Tables.

These CTT names shall be used whenever the Common Template Tables are referred to externally in a given context, whether in a process, contract, or procurement requirement. If another name is used due to practical constraints, a declaration of conformance shall indicate the correspondence between this other name and the CTT names.

The use of defined names is necessary to manage the different stages of development of these tables. This follows from the nature of the reference character repertoire, for which development will be ongoing for a number of years or even decades.

## Annex A

(normative)

## Common Template Tables

The Common Template Tables are provided separately in machine-readable file as normative components of this document.

The latest version of the Common Template Table deprecates previous versions of the CTT. However, it does not preclude specific reference to the previous tables, which contained and still contain ordering information applicable to the repertoires of previous versions of ISO/IEC 10646 and their amendments.

Starting with ISO/IEC 10646:2020 $6^{\text {th }}$ Edition Amendment 2, the Common Template Tables are posted as version-specific files in the Unicode website at https://www.unicode.org/Public/CTT/. Each version of the Common Template Table is named using the Unicode Version usually synchronized with a specific repertoire of ISO/IEC 10646.

NOTE 1 - For example, the repertoire of ISO/IEC 10464:2020 6th Edition Amendment 2 corresponds to the repertoire of Unicode Version 16.0 repertoire. Therefore, the related Common Template Table name is CTT_V16_0.

The CTTs created prior to ISO/IEC 10646:2020 $6^{\text {th }}$ Edition Amendment 2 can be found at the following URLs. French versions of the same files which only differ in their comments (their technical comments are identical ) can be found in adjacent folders with 'fr' replacing 'en' in their file names.

- [ordering information on the repertoire of characters as defined in ISO/IEC 10646-1:1993 including Amendments 1-9] https://standards.iso.org/iso-iec/14651/ed-1/ISO14651 2000 TABLE1 en.txt
- [ordering information on the combined repertoire of characters of ISO/IEC 10646-1:2000 and ISO/IEC 10646-2:2001] https://standards.iso.org/iso-iec/14651/ed-1/IS014651 2002 TABLE1 en.txt
— [ordering information on the repertoire of characters as defined in ISO/IEC 10646:2003] https://standards.iso.org/iso-iec/14651/ed-1/ISO14651 2003 TABLE1 en.txt
- [ordering information on the repertoire of characters as defined in ISO/IEC 10646:2003] including Amendment 1 https://standards.iso.org/iso-iec/14651/ed-1/IS014651 2005 TABLE1 en.txt
- [ordering information on the repertoire of characters as defined in ISO/IEC 10646:2003 including Amendments 1-2] https://standards.iso.org/iso-iec/14651/ed-2/ISO14651 2006 TABLE1 en.txt
- [ordering information on the repertoire of characters as defined in ISO/IEC 10646:2003 including Amendments 1-4] https://standards.iso.org/iso-iec/14651/ed-2/ISO14651 2008 TABLE1 en.txt
- [ordering information on the repertoire of characters as defined in ISO/IEC 10646:2011] https://standards.iso.org/iso-iec/14651/ed-3/ISO14651 2010 TABLE1 en.txt

To meet cultural requirements of specific communities, delta declarations will have to be applied to the amended table as defined in this document.

## Annex B <br> (informative) <br> Example tailoring deltas

## B. 1 Example 1 - Minimal tailoring

The following is a minimal tailoring of the Common Template Table.

```
reorder after <SFFFF>
order_start forward;forward;forward;forward
reorder-end
```

## B. 2 Example 2 - Reversing the order of lowercase and uppercase letters

The following is a simple tailoring example to show how to reverse the order of uppercase versus lowercase from the order specified in the Common Template Table.

```
% Make uppercase letters sort before lowercase
% and scanning of accents done forward at level 2.
% The entire range of tertiary weight symbols
% <MIN>..<CIRCLE> are moved after <CIRCLECAP>, so that they order after
% <CAP> <WIDECAP> <COMPATCAP <FONTCAP> <CIRCLECAP> in the same
% relative order with respect to themselves. This has the effect of
% also making all the compatibility uppercase letters sort before
% their respective compatibility lowercase letters. (For example,
% U24B6 CIRCLED LATIN CAPITAL LETTER A will sort before
% U24D0 CIRCLED LATIN SMALL LETTER A.
% To do this correctly, an order_start is
% inserted to make the delta conformant.
reorder-after <CIRCLECAP>
<MIN>
<WIDE>
<COMPAT> <FONT>
<CIRCLE>
reorder after <SFFFF>
order_start forward;forward;forward;forward,position
reorder-end
% End of the uppercase/lowercase tailoring
```

## B. 3 Example 3 - Canadian delta and benchmark

This annex describes benchmark 1, based on Canadian standard CAN/CSA Z243.4.1-1998 (and 1992). The delta that precedes the benchmark has been simplified for illustration here; a larger delta is required, mainly for special characters, for full conformance to this Canadian standard, and is given here as an example only, limited to what is required for the benchmark. For complete information, the Canadian standard CAN/CSA Z243.4.1 should be consulted. The example tailoring is to be applied to the Common Template Table 'ISO14651_2002_TABLE1' as referenced by Annex A, with the following delta.
a) Level processing properties:
forward; backward; forward; forward,position
b) Number of levels: Four (unchanged).
c) No symbol changes.
d) The following ordering changes are done:
— æ sorted as if it were separate letters "ae" at level 1. The letters "ae" are distinguished at level 2 from the character "æ" and is ordered before it;
— ð sorted as if it were the letter "d" at level 1. The letter "ð" is distinguished at level 2 from the letter "d" and is ordered after it;
— p sorted as if it were separate letters＂th＂at level 1．The letters＂th＂is distinguished at level 2 from the letter＂ b ＂and is ordered before it．
A Canadian tailoring expressed in the tailoring syntax for this document（normative only for Annex A）can be：

```
% copy ISO14651_2002_TABLE1
reorder-after <SFFFF>
order_start forward;backward; forward; forward,position
<U00E6> "<S0061><S0065>";"<BASE><VRNT1><BASE>";"<MIN><COMPAT><MIN>";

## B. 4 Example 4 - Danish delta and benchmark

The following is a Danish example tailoring delta. This formal specification corresponds to Danish standard DS 377 and to "Retskrivningsordbogen", the Danish orthography specification. The example tailoring is to be applied to the Common Template Table 'ISO14651_2002_TABLE1' as referenced by Annex A

```
% This tailoring is in accordance with Danish Standard DS 377 (1980)
% and the Danish Orthography Dictionary (Retskrivningsordbogen par 4,
% 1986). It is also in accordance with Greenlandic orthography.
collating-symbol <LIGHT> % Symbolic weight for lighter than <BASE>
% Define collating elements for <AA> - LETTER A WITH RING ABOVE
% and combinations with combining accents
collating-symbol <A-A> % symbolic weight for <AA>
collating-element <A-plus-combining-ring> from "<U0041><U030A>"
collating-element <a-plus-combining-ring> from "<U0061><U030A>"
% Define collating elements for sequences of a-plus-a
collating-element <A-plus-A> from "<U0041><U0041>"
collating-element <A-plus-a> from "<U0041><U0061>"
collating-element <a-plus-A> from "<U0061><U0041>"
collating-element <a-plus-a> from "<U0061><U0061>"
% Define collating elements for combinations with combining accents
collating-element <U-plus-combining-diaeresis> from "<U0055><U0308>"
collating-element <u-plus-combining-diaeresis> from "<U0075><U0308>"
collating-element <U-plus-combining-doubleacute> from "<U0055><U030B>"
collating-element <u-plus-combining-doubleacute> from "<U0075><U030B>"
collating-element <O-plus-combining-diaeresis> from "<U004F><U0308>"
collating-element <o-plus-combining-diaeresis> from "<U006F><U0308>"
```

```
collating-element <O-plus-combining-doubleacute> from "<U004F><U030B>"
collating-element <o-plus-combining-doubleacute> from "<U006F><U030B>"
collating-element <A-plus-combining-diaeresis> from "<U0041><U0308>"

reorder-after <BASE>
<LIGHT>
<BASE>
% A list of reweighting statements to deal with specific collation
% behaviour for Danish. All of these define or redefine weight_list's,
% and so the entire block could simply be reordered after the
% order-start entry in the table. However, for clarity here and for
% stability, each separate set of weightings is reordered locally in
% the table around the first entry for that set of weightings.
% Actually a number of other reweighting statements should be specified
% with respect to the ISO/IEC 14651 table so that all accents be
% ignored on the first level, while the }14651\mathrm{ table distiguish
% for example between different accented versions of <l> and a number
% of other latin letters. This is considered less important
% and too elaborate for this example.
% Also this example delta does not include specifications for reordering
% of special characters like the currency denominators DOLLAR SIGN,
% CENT SIGN, and POUND SIGN, and unit denominators like the
% ANGSTROM SIGN, which have first-level weights in the CTT, while
% rules in DS 377 prescribe that special characters are ignored.

## B. 5 Example 5 - A tailoring for Khmer

The Khmer script is mainly used in Cambodia. The tailoring given below is not included in the CTT (see Annex A) itself in order to keep the CTT simple, especially for rare letterforms. For example, the Khmer ROBAT for which the tailoring below may not be desirable for efficiency reasons, since this letter occurs very rarely, but the tailoring for handling it correctly may affect the efficiency of collation also for texts that do not contain any ROBAT.

## Annex C

(informative)
Preparation

## C. 1 General considerations

Preparation is necessary only for modification and/or duplication of original strings to render them con-text-independent prior to the comparison phase. A non-duplicating preparation maps a given string to one string. A non-duplicating preparation can be composed with the key generation and comparison, as, for example, is needed for Lao and Thai (see C.2), or proper ordering of numerals (see C.3). A duplicating preparation can map a given string to several strings (to be sorted).

Examples of non-duplicating preparations are the following:

- vowel-consonant rearrangement, as is needed for Thai (see C.2) and Lao;
- transformation of numbers so that the result will be ordered in numerical order, as opposed to positional order (see C.3). Numeric ordering is particularly delicate and requires special consideration in many cases;
- removal or rotation of characters that are a nuisance for special requirements of ordering; for example, removing articles (language dependent) in sorting book names as in

```
Tale of two cities, A
```

- transformation of abbreviated data into a fuller form. For example: transformation of "McArthur" to give "MacArthur".

Some examples of a duplicating preparation are the following:

- duplicating a string into several "rotations", like when producing a keyword-in-context index; International string ordering

International string ordering
International string ordering
— duplication of a string such as "41" for as it is spelled out in different languages (Irish Gaelic, German, English, and French).

forty-one
quarante et un

## C. 2 Thai string ordering

## C.2.1 General

This Clause explains some of the principles behind the tailoring of the CTT given in B.5, as well as the CTT ordering for Thai (and to some extent Lao).

## C.2.2 Thai ordering principles

The widely accepted standard for Thai lexicographical ordering is defined in the Royal Institute Dictionary 2542 B.E. Edition (1999 A.D.), the official standard Thai dictionary. The ordering principles, expanded to cover the full range of the Thai script and its computerisation are as follows.

- Words are ordered alphabetically, not phonetically. Consonants order is:

ก ข ๆ ค ค ฆ ง จ ฉ ช ซ ฌ ญ ฎ ฎ 玉 ฑ ฒ ณ ด ต ถ ท
ธนบปผฝ พ ฟ ภ มยร ฤล ภ ว ศ ษ ส ห ฬ อ ฮ

- Vowels, and nikhahit, are also ordered by written forms, not by sounds. Vowels and nikhahit order is:

อ ว ย are always ordered as consonants, although they sometimes act as vowels;
7 is a long-legged variant of 七, used with the long-legged consonants ฤ and ภ: ฤา and ภา;
ㄱ is logically an ffollowed by a ${ }^{\circ}$. However, the Unicode compatibility decomposition of the precomposed character is to a ${ }^{\circ}$ followed by an 7 , so this misspelling shall be handled as well.

- No syllable structure or word boundary analysis is required, as Thai lexicons are ordered alphabetically, not phonetically. Note that Thai normally does not use any word separator, except, and exceptionally, zero width space.
- String comparison is performed from left to right, but treating leading vowels (b- แ- โ- ?- ไ-, corresponding to characters U0E40-U0E44), as though they followed the consonant that immediately follows them. Therefore, rearrangement (in some way) is needed before comparison.
- Tones and diacritics are ignored at level 1. At level 2 their order is:

- Since Thai, Lao, and Khmer are uncased, it may seem that the third level is not needed for Thai, Lao, and Khmer string ordering. However, the third level is used to differentiate LAKKHANGYAO (7) as a variant of SARA AA (7), since similar variants in other scripts are differentiated in a like manner at level 3, as well as for other variation cases in Thai, Lao, and Khmer.
- When Thai punctuation marks ( $\mathrm{C}_{\mathrm{m}}$ था ฯ ๑ๆ) are concerned, another level of weights is required for them. This corresponds to the fourth level in the Common Template Table. In string ordering, punctuation marks are less significant than any tone marks and diacritics, and shall be ignored in all the first three levels. Note that PAIYANNOI (ฯ) and THAI CHARACTER MAIYAMOK (repeat mark ๆ) are regarded and ordered as punctuation marks, not letters, despite their Unicode general category as "Lo" and "Lm" respectively. For example, "ข้างๆ, ข้างกบ. ข้างๆ คๆ, ข้างจัน" is a valid order in the Royal Institute Dictionary. In the first level, the considered weights correspond to ขาง, ขางกบ, ขางคู, and ขางจนั respectively.
- The ten Thai decimal digits (ం ๑๒ ๓ ๔ ๕ ๖ ๗ ๘ ๙) , each semantically equivalent to Arabic digit 09 , respectively. Their weights are then equal to their corresponding Arabic digit in the first level, and are different in the second level, to distinguish script.

## C.2.3 Thai ordering principles

Regarding the handling of pre-vowels, either a collation preparation or collating-element grouping (as in the tailoring in B.5) is required. The collation preparation scans the string once and swaps every leading Thai vowel with its succeeding character (ideally only if the succeeding character is a Thai consonant). The prepared string is then passed to the normal weight calculation process. Another way to manage this is by means of collating-element formation - the approach taken both by the Common Template Table and by the collation weighting table of the Unicode Collation Algorithm (see Clause 2). Every possible pair of leading vowel and consonant is defined as a collating-element, whose weight is equal to that of the rearranged substring. In addition, since two $t$ in sequence look just like a $b$, two $t$ in sequence should be handled just like a แ.

Note that the rearrangement of each leading vowel is simply performed with its immediate succeeding consonant. No consonant cluster analysis is needed. Indeed, doing so would result in ambiguities or yield a different order than that specified in the Royal Institute Dictionary. Below are the examples.
a) Ambiguities: The problem with ambiguity is illustrated by the word "เพลา". It has two potential pronunciations: either as a two-syllable word, "phe-la" (meaning "time"), or as a one-syllable word, "phlao" (meaning "axle" or "abate"). A rearrangement algorithm which follows the distinct pronunciation of the potential cluster 'พล' in this string would result in distinct keys, "พเลา" and "พลเา", and therefore different weights, which are equally legal. Both words need to have the same weight to be sortable, however.
b) Non-conforming ordering: To illustrate the difference in ordering caused by the treatment of consonant clusters, consider these words, shown in conforming order: "เพล, เพลง, เพศ". The correct rearrangement ignores any clusters and results in the following: "พเล, พเลง, พเศ", which sorts in the order shown. If, however, pairs of consonants that form legal clusters were grouped as single collation elements (regardless of actual pronunciation where the potential pronunciation is ambiguous), then the results of rearrangement would be "<พล>เ, <พล>เง, พเศ", which would yield the (non-conforming) ordering "เพศ, เพล, เพลง". Again, if actual clusters were grouped as single collation elements (with some disambiguation effort), then the results of rearrangement would be "พเล, <พล>เง, พเศ", which would yield the (non-conforming) ordering "เพล, เพศ, เพลง".

## C.2.4 Example of ordered strings

| Here is an ordering example: Example for Thai (sorted order) |  |  |  |
| :---: | :---: | :---: | :---: |
| กก กรรม กรรม์ -กระแย่ง กราบ กะเกณฑ์ กัก ก้าว กำ กิน กี่ กึนं กุน กูด เก้ง เกล้า เกลียว เก้า เกาะ เกี่ยว เกียะ เกือก แกง แกะ | โกน <br> โกร๋น <br> ใกล้ <br> ไก่ <br> ไกล <br> ข้น <br> ขนาบ <br> ข้าง <br> ข้างๆ <br> ข้างกระดาน <br> ข้างขึ้น <br> ข้างควาย <br> ข้างๆ คูๆ <br> ข้างเงิน <br> ข้างออก <br> เข็ด <br> เขน <br> เข็น <br> เข่น <br> แข็ง <br> แข่ง <br> แข้ง <br> แข้งขวา <br> แข็งขัน | แข่งขัน <br> แขน <br> ครรภ- <br> ครรภ์ <br> จุมพล <br> จุพล <br> ชาย <br> เฒ่า <br> เณร <br> ตลาด <br> ทูลเกล้า <br> ทูลเกล้าฯ <br> ทูลเกล้าทูลกระหม่อม <br> น้า <br> นำ <br> นี้ <br> บุญหลง <br> บุญ-หลง <br> ปา <br> ป่า <br> ป้า <br> ป็า <br> ป่า <br> ปาน | ผัด <br> ฯพณฯ <br> พณิชย์ <br> ย่อง <br> รอง <br> ฤทธิ์ <br> ฤษี <br> ฤาษี <br> ลลิตา <br> ภาชา <br> วก <br> ศาล <br> หริภุญชัย <br> หฤทัย <br> หลง <br> แหง <br> แห่ง <br> แหนม <br> แหนหวง <br> แหบ <br> แหม <br> อาน <br> ฮา |

## C. 3 Handling of numeral substrings in collation

## C.3.1 General

A numeral is a string representing a number. The examples here deal with numerals that represent values in $R$, the real numbers, or really, subsets of $R$, as these have a predetermined order. Only decimal numerals are dealt with in the examples given here.

The presentation below will first give positional system decimal numerals for natural numbers using the digits $0-9$. It will progress to numerals for whole numbers, numerals with a fraction part, a fraction part, and an exponent. There is also a brief discussion on numerals with digits from other scripts, scripts that sometimes uses another syntax with digits for numerals (such as Han numerals), and Roman numerals. There are circumstances where digits do not represent numerical values, such as in part numbers and telephone numbers. The preparations described below have undesirable consequences in cases where apparent numerals do not represent numerical values, such as when the ordering telephone numbers or part "numbers", and should be avoided in those cases.

## C.3.2 Handling of "ordinary" numerals for natural numbers

The Common Template Table have no means of ordering strings with numbers in such a way that the resulting order reflects the number values represented by the numerals. For example, given the following randomly arranged strings:

- Release 1
- Release 20
- Release 12
- Release 2
- Release 9
the method described in this document yields the following order for these strings:
- Release 1
- Release 12
- Release 2
- Release 20
- Release 9
(It is sufficient simply to look positionally at just the first digit in each numeral to see why this ordering results.) A more acceptable ordering is as follows.
- Release 1
- Release 2
- Release 9
- Release 12
- Release 20

The Common Template Table cannot be tailored to give this result. However, preparation can be done prior to the basic collation step to achieve the desired results when numeric value order is desired. The prepared strings are normally not presented to the user; only the original strings are. The prepared strings are normally only used for the collation key construction. A simple, but not very general, way of preparing numerals for natural ordering is to pad them with zeroes to a given number of digits. If one pads the numerals in our original example strings up to three digits, the result will be the following.

- Release 001
- Release 020
- Release 012
- Release 002
- Release 009

Using the Common Template Table, one then obtains the strings in a better order (here showing the strings as they are after preparation, which are normally not shown in the result).

- Release 001
- Release 002
- Release 009
- Release 012
- Release 020

However, there are two problems with this approach.

- One needs to determine beforehand a (usually small) number of digits to pad up to. If the number of digits to pad up to is too large, the strings after preparation can become rather long, especially if there are several numerals in each string. If the number of digits to pad up to is too small, however, the risk is greater that there are actually occurring numerals with more digits than one has padded up to, which results in partially getting back to the original situation, where the numerals' values are not taken entirely into account.
- Determinacy is lost, if some of the original numerals were already partially zero-padded. For example, if the original strings were:
- Release 01
- Release 1
the strings after preparation are identical, and the end result (as the user would normally see it) could be either:
- Release 01
- Release 1
or
- Release 1
- Release 01
and the relative order may come out differently for different occurrences of numerals or different runs of the collation process applying the same rules. This kind of indeterminacy is undesirable.
There are many ways to deal with these problems. The following is one such way.
To each maximal digit subsequence prepend a fixed-number-of-digits numeral which represents the original number of digits in the numeral. For most cases, a two-digit count would suffice (allowing up to 99 digits in the original integer numerals). For example, given the original strings:
- Release 1
- Release 01
- Release 20
- Release 12
- Release 2
- Release 09
- Release 9
one obtains after this preparation the following strings:
- Release 011
- Release 0201
- Release 0220
- Release 0212
- Release 012
- Release 0209
- Release 019
which would be ordered by the basic mechanism of this document to:
- Release 011
- Release 012
- Release 019
- Release 0201
- Release 0209
- Release 0212
- Release 0220
and are normally presented to the user as:
- Release 1
- Release 2
- Release 9
- Release 01
- Release 09
- Release 12
- Release 20

This particular method puts numerals with a like original number of digits close to each other, even if the actual value represented is smaller due to the original zero-padding. If the represented values should be kept close together, one should instead duplicate the numeral: first, a count of digits for the leadingzerostripped numeral, the leading-zero-stripped numeral itself, followed by the original numeral. The duplication is needed to get determinacy relative to the original strings. For example, using the same original strings as above:

- Release 0111
- Release 01101
- Release 022020
- Release 021212
- Release 0122
- Release 01909
- Release 0199
which would be ordered by the basic mechanism of this document to:
- Release 01101
- Release 0111
- Release 0122
- Release 01909
- Release 0199
- Release 021212
- Release 022020
and normally be presented to the user as:
- Release 01
- Release 1
- Release 2
- Release 09
- Release 9
- Release 12
- Release 20

The originally zero-padded numerals consistently come before the numeral without (or with less) original zero-padding. The preparation processing could move the original numerals (in order of occurrence) to the very end of each string, if one wants to give the original zero-padding lesser significance than the text following the numerals.

The presence of several natural numerals in each string causes no additional problem.
Taking care of the natural number numerals is, in most cases sufficient, and it is recommended that it be included as part of the usual preparation of strings to be collated. However, such preparation is not required by this document.

## C.3.3 Handling of positional numerals in other scripts

ISO/IEC 10646 encodes decimal digits for a number of scripts. In most cases, these are used in a positional system, just like 0-9 usually are. However, one should not regard a sequence of numerals mixed from different scripts as a single numeral; rather, one should consider each maximal substring of digits of the same script to be a numeral.

## C.3.4 Handling of other non-pure positional system numerals or non-positional system numerals (e.g. Roman numerals)

Chinese and some other languages can use decimal digits (in the Han script, for instance) interspersed with ideographs for "one thousand", "ten", etc. If such numerals are to be collated according to the value they represent, one can proceed as above, adding a step just after the initial duplication: convert the copy to the corresponding positional system numeral in the syntax used here for whole numerals.

Roman numerals, if handled, can be handled in a similar fashion to that described above. Duplicate and replace the first copy with the same natural number expressed in the decimal positional system. For example, "Louis V", where the V is determined to be a Roman numeral, can be modified to "Louis 5 V ".

Caveat: In this case, human interactive intervention or an expert system may be required, as in the following example involving the French language: CHAPITRE DIX might mean CHAPTER 10 or CHAPTER 509 ("dix" is the French word for 10, it is also the Roman numeral for 509).

## C.3.5 Handling of numerals for whole numbers

If numerals for negative whole numbers are also to be ordered according to their value, there are a number of issues to be considered. Most frequently, negative whole values are given numerals that begin with a negation sign. The negation sign may be HYPHEN-MINUS U002D (but this character may often represent a true hyphen, rather than a negation), or MINUS SIGN U2212. However, there are other conventions also, like using a SOLIDUS U002F or a PERCENT SIGN U0025 to indicate negativity; or the negation indicator can come after the digits rather than before; or negativity can be indicated by putting the digits between parenthesis, and/or putting the digits in a contrasting colour (often red). In the examples here, only the case that negativity is indicated by an immediately prepended MINUS SIGN is dealt with. Positivity is indicated by either the absence of a MINUS SIGN, or the presence of a PLUS SIGN U002B.

Example strings:

- Temperature: $-9^{\circ} \mathrm{C}$
- Temperature: $0^{\circ} \mathrm{C}$
- Temperature: $-14{ }^{\circ} \mathrm{C}$
- Temperature: $05^{\circ} \mathrm{C}$
- Temperature: $+5^{\circ} \mathrm{C}$
- Temperature: $-0^{\circ} \mathrm{C}$
- Temperature: $-09^{\circ} \mathrm{C}$
- Temperature: $105^{\circ} \mathrm{C}$
- Temperature: $+05^{\circ} \mathrm{C}$
- Temperature: $5^{\circ} \mathrm{C}$

One preparation to get an acceptable and determinate order for numerals (in this syntax) for whole numbers is as follows (actual implementations should do something equivalent, but more efficient).
a) Duplicate the numerals in the string (including sign indications), putting the "original" ones (not to be touched by the following steps) in order of original occurrence at the end or the string, leaving the copies to be modified at the original positions. This step ensures determinacy.
b) Ensure that all of the copies have an explicit initial sign indicator.
c) Remove leading zeroes in the copies of the numerals (systematically either leaving one zero digit for zero or representing 0 by the empty string of digits); alternatively, let all numeral copies have exactly one leading zero.
d) Between the sign indicator and the digits in the copies of the numerals, insert a (two-digit) count of how many digits there were (after removing the leading zeroes).
e) Do 9 s complement on each digit in each copy of a negated numeral. 9 s complement of a digit that individually represents the value $x$, is $9-x$. That is, 9 s complement of 0 is 9 , of 9 is 0 , of 5 is 4 , etc.

For the basic collation step, use a tailoring of the template given in this document, namely, a tailoring where the PLUS SIGN and the MINUS SIGN are significant at the same level as the digits, and where the MINUS SIGN has less weight than the PLUS SIGN (in the example below, it is assumed that the weight of PLUS SIGN is less than the weight of 0 , but this is not a prerequisite for getting an acceptable ordering).

Our example strings after this preparation:

- Temperature: $-980^{\circ} \mathrm{C}-9$
- Temperature: $+00^{\circ} \mathrm{C} 0$
- Temperature: $-9785^{\circ} \mathrm{C}-14$
- Temperature: $+015{ }^{\circ} \mathrm{C} 05$
- Temperature: $+015{ }^{\circ} \mathrm{C}+5$
- Temperature: $-99^{\circ} \mathrm{C}-0$
- Temperature: $-980^{\circ} \mathrm{C}-09$
- Temperature: $+03105^{\circ} \mathrm{C} 105$
- Temperature: $+015{ }^{\circ} \mathrm{C}+05$
- Temperature: $+015{ }^{\circ} \mathrm{C} 5$

The ordering for these, using the basic mechanism of this document, is:

- Temperature: -9 $785^{\circ} \mathrm{C}-14$
- Temperature: $-980^{\circ} \mathrm{C}-09$
- Temperature: $-980^{\circ} \mathrm{C}-9$
- Temperature: $-99^{\circ} \mathrm{C}-0$
- Temperature: $+00^{\circ} \mathrm{C} 0$
- Temperature: $+015^{\circ} \mathrm{C}+05$
- Temperature: $+015{ }^{\circ} \mathrm{C}+5$
- Temperature: $+015^{\circ} \mathrm{C} 05$
- Temperature: $+015{ }^{\circ} \mathrm{C} 5$
- Temperature: $+03105^{\circ} \mathrm{C} 105$
and normally presented to the user as:
- Temperature: $-14^{\circ} \mathrm{C}$
- Temperature: $-09^{\circ} \mathrm{C}$
- Temperature: $-9^{\circ} \mathrm{C}$
- Temperature: $-0^{\circ} \mathrm{C}$
- Temperature: $0^{\circ} \mathrm{C}$
- Temperature: $+05^{\circ} \mathrm{C}$
- Temperature: $+5^{\circ} \mathrm{C}$
- Temperature: $05^{\circ} \mathrm{C}$
- Temperature: $5^{\circ} \mathrm{C}$
- Temperature: $105^{\circ} \mathrm{C}$

This preparation results in a determinate ordering of strings that have zero or more numerals for whole numbers in them, such that the numerals are ordered according to the integer value they represent.

The process for other syntaxes for whole numbers can be similar. Just add a step to convert the copies to the syntax used here for whole numbers.

This technique for handling negative numerals can be used also for numerals with a fractional part and so on (see C.3.6).

## C.3.6 Handling of positive positional numerals with fractional parts

The method presented in C.3.5 can easily be adapted to the case where fraction parts may occur and are to be taken into account. A problem is, however, that the characters often used to delimit the integer part from the fraction part are also used for other purposes. The separator character is generally either FULL STOP U002E, or COMMA U002C. These characters also have other uses, also in conjunction with digits.

For the examples here, assume that FULL STOP is used (only) as a fraction part delimiter.
Do as in C.3.5, but count only the digits in the integer part of the numeral for the count of digits to be prepended. The fraction part delimiter character (here: FULL STOP) can be removed.

For example:

- -12.34
- 12.34
- 3.1415
- 3.14

After preparation:

- -978765-12.34
- +021234 12.34
- +013.1415 3.1415
- +013143.14

Ordered:

- -978765-12.34
- +013143.14
- +01314153.1415
- +021234 12.34

As presented to the user:

- -12.34
- 3.14
- 3.1415
- 12.34 .

## C.3.7 Handling of positive positional numerals with fraction parts and exponent parts

For very large, or very small, values, one often uses formats like $2,5 \times 10^{7}$ (to illustrate just one possible way of writing these for the purposes of these examples). Here, there is already an exponent, which shall be combined with the "number of integer part digits" (here: digits before the decimal point), by adding those two numbers to get a resulting fixed-number-of-digits exponent to prepend just before the first digit. For this example, with a three-digit exponent: we get +00825 . One problem here is that the resulting exponent may be negative. To handle this, use an exponent bias. For a three-digit exponent a bias of 500 may be suitable, which gives us for this example numeral: +50825 , and for the numeral $2,5 \times 10^{-7}$, we get +49425 . Negative values are handled as before, with 9's complement. $-2,5 \times 10^{7}$ gives -49174 , and $-2,5 \times 10^{-7}$ gives -50574 . This method should be familiar to anyone with knowledge about (radix 10) floating point arithmetic.

Thus:
$-2,5 \times 10^{-7}$
$--2,5 \times 10^{7}$
$-2,5 \times 10^{7}$

- $-2,5 \times 10^{-7}$

After preparation (including a duplicate of the original, for determinacy):

- +49425 2,5 $\times 10^{-7}$
- $-49174-2,5 \times 10^{7}$
- +50825 $2,5 \times 10^{7}$
$-\quad-50574-2,5 \times 10^{-7}$
Ordered:
- $-49174-2,5 \times 10^{7}$
- $-50574-2,5 \times 10^{-7}$
$-+494252,5 \times 10^{-7}$
- +50825 $2,5 \times 10^{7}$

As presented to the user:
$-\quad-2,5 \times 10^{7}$

- $-2,5 \times 10^{-7}$
$-2,5 \times 10^{-7}$
$-2,5 \times 10^{7}$

## C.3.8 Handling of date and time of day indications

Going a bit beyond plain numerals, date and time-of-day indications often employ numerals (as well as names for months, weekdays, etc.) for the parts of the date and time-of-day indication. It is not uncommon to want to order this kind of information also when it occurs within strings.

The preparation needed to obtain date and time-of-day indications, of some predetermined syntaxes, ordered according to point in time is similar to what has been described in C. 3 in general:
a) Duplicate all date and time-of-day indications to maintain determinacy of collation when the original strings differ but point in time identical. Leave the originals at the end of the strings, untouched by the following steps.
b) Convert the copies of the date and time indications to the same calendar system, if there are several calendar (sub)systems used and handled. The calendar (sub)system converted to, shall be suitable for being able to get proper time order. We will here use the Gregorian calendar system and the subsystem of year, month, day-of-month.
c) Put the date and time-of-day elements in order of decreasing significance (to the resolution taken into account): Full year, month, day-of-month, hour, minute, second, fraction of second.
d) Use a 24-hour/day clock for the time-of-day indications. Remove A.M. or P.M. indications, if present and handled, in the date-time indication copies.
e) Use the UTC (Co-ordinated Universal Time) time zone for the date and time-of-day indications. Remove time zone indications, if present, in the date-time indication copies.
f) Use month numbers, rather than month names. Use two digits each for month, day-of-month, hour, minute, second.
g) Use full year number representation, as many digits as needed. Take abbreviations into account so that the full year number is used. For example, ' 98 ' might denote year 98 or year 1998, or 1898, etc. No indeterminacy regarding year due to abbreviations like these may be present after the preparation step.
h) For years AD, use an initial PLUS SIGN. For years BC, use an initial MINUS SIGN. Remove the original AD or $B C$ indication from the copies. (To nitpick, year $n B C$ should be represented by year (1-n), which is less or equal to zero if $n$ is positive.)
i) For the year indications, insert between the sign indication and the first digit for the year indication a digit telling how many digits there are in the full year indication. One digit for this should suffice.
j) For negative years, replace each digit in the year indication (including the digit telling the number of digits in the original full year indication) with its 9 s complement digit.
k) Make sure the textual format for all of the date indication copies is the same (paying attention to hyphens, spaces, etc.). (This is most easily accomplished by printing them in the same format from an internal, non-string, representation.)
l) Alternatively, use a number indicating the point of time on a linear time scale (for example, hours, milliseconds, or days from a predetermined point in time), to the resolution desired, and handle this as an ordinary numeral (see above).

For the basic collation step, use a tailoring of the template given in this document. Use a tailoring where the PLUS SIGN and the MINUS SIGN are significant at the same level as the digits, and where the MINUS SIGN has less weight than the PLUS SIGN.

For example:

- Dated: July 19, 1955, at 1 p.m. GMT
- Dated: January, 20 BC
- Dated: Sept. 20, 1995, at 1 p.m. PST
- Dated: 11-june/345 AD

After preparation:

- Dated: +41955-07-19T13:00Z July 19, 1955, at 1 p.m. GMT
- Dated: -780-01 January, 20 BC
- Dated: +1995-09-20T10:00Z Sept. 20, 1995, at 1 p.m. PST
— Dated: +3345-06-11 11-june/345 AD
Ordered:
- Dated: -780-01 January, 20 BC
— Dated: +3345-06-11 11-june/345 AD
- Dated: +41955-07-19T13:00Z July 19, 1955, at 1 p.m. GMT
- Dated: +41995-09-20T10:00Z Sept. 20, 1995, at 1 p.m. PST

As presented to the user:

- Dated: January, 20 BC
- Dated: 11-june/345 AD
- Dated: July 19, 1955, at 1 p.m. GMT
- Dated: Sept. 20, 1995, at 1 p.m. PST.

## C.3.9 Making numbers less significant than letters

In many cases, numerals preceding letters should be considered as less significant than the following alphabetic part. However, the Common Template Table specifies digits to be level 1 significant. To make numerals less significant than letters, either tailor the weight table so that numerals are ignored at level 1 (but significant at level 2 or 3), or alternatively leave them significant at level 1, but prepare the strings so that numerals are moved to the end of the string or moved to a less significant field. When doing such a move, one needs to pay attention not to map different strings to identical strings (or identical string fields), so that determinacy is maintained (see C.3.8).

Some examples where it is appropriate to consider numerals as less significant than letters: street or block names with one or more numbers to indicate where in the street/block, if that/those number(s) precede the street or block name (common for example in the US and in Japan); chemical compound names which have prepended numerals, for example, 1,2-diclorobenzol.

## C.3.10 Maintaining determinacy

As noted in C.3.8 in several cases, part of the string has been duplicated to maintain determinacy in collation, when the original strings are different, but when preparation may otherwise turn different strings into identical strings.

This method of concatenating a copy of a substring in order to maintain determinacy can be used more generally, so if there are several preparations affecting different parts of the strings, one may simply duplicate the original strings to begin with, and only perform the preparation (without additional copying) on the given string, then concatenating on the initial copy.

One disadvantage with just concatenating the two copies is that the base letters of the second half of the "doubled" string count as more significant than the accents and case of the resulting first half of the "doubled" string. This document has no mechanism for handling this in a better way, where the "original" (the second half of the "doubled" string) would count as less significant than the entire first half of the "doubled" string. This may be handled better by having the original and copy in different "fields", and construct the collation key by combining the full keys for each "field". Such processing is beyond the scope of this document, however.

Maintenance of determinacy when some of the original strings to be collated are identical, is out of the scope of this document. A sorting processor should document if it is "stable" (maintaining initial relative order of identical strings) or not. This is useful to know when sorting on one field of multi-field data.

## C. 4 Pre-processing Hangul

## C.4.1 General

In general, one needs to handle not only modern complete Hangul syllables, but also old and/or incomplete syllables to collate Hangul data properly. When Hangul data in ISO/IEC 10646 is input to an algorithm supporting this document, it is not always collated properly. Therefore, one needs to preprocess these data so that this problem can be fixed. Of course, depending on the specific collation desired (for example, the Republic of Korea and DPRK have different collation orders), some tailoring of the CTT table may be required.

The main purpose of the pre-processing is, after syllable boundaries are determined, to transform one complete or incomplete syllable into 9 simple letters.

Suppose that one has Hangul data represented using Hangul letters (Jamos) U11xx/UA9xx/D7xx and/ or Hangul Wanseong syllables UAC00..UD7A3. The pre-processing steps 1 to 3 are as described here.

## C.4.2 Step 1

If a syllable is represented with a Wanseong syllable character UAC00.. UD7A3, it is decomposed into sylla-ble-initial, syllable-peak and optionally syllable-final parts as follows.

Find the syllable component indices I, P, F calculated in ISO/IEC 10646:2020, sub-clause 27.10, item d).
a) The code position of a syllable-initial letter is $\mathrm{U}+1100+\mathrm{I}$. Example: If I is 17 ( $0 \times 11$ in hexadecimal), then the code position is $U+1111$.
b) The code position of a syllable-peak letter is $\mathrm{U}+1161+\mathrm{P}$. Example: If P is 16 ( $0 \times 10$ in hexadecimal), then the code position is $\mathrm{U}+1171$.
c) If F is zero, there is no syllable-final letter. Otherwise, the code position of a syllable-final letter is $\mathrm{U}+11 \mathrm{~A} 7+\mathrm{F}$. Example: If F is $18(0 \times 12$ in hexadecimal), then the code position is $\mathrm{U}+11 \mathrm{~B} 9$.

## C.4. 3 Step 2

Each of a syllable-initial, syllable-peak or syllable-final parts (simple or complex) of a complete or incomplete syllable is transformed into 3 simple letters.
a) If a syllable-initial part of a syllable is composed of only one simple letter (<si1>), then that part is transformed into "<si1> U+0000 U+0000". For example, $\mathrm{U}+1100 \rightarrow \mathrm{U}+1100 \mathrm{U}+0000 \mathrm{U}+0000$.
b) If a syllable-initial part of a syllable is composed of two simple letters (<si1> <si2>), then that part is transformed into "<si1> <si2> U+0000". For example, U+1101 $\rightarrow \mathrm{U}+1100 \mathrm{U}+1100 \mathrm{U}+0000 ; \mathrm{U}+1100$ $\mathrm{U}+1100 \rightarrow \mathrm{U}+1100 \mathrm{U}+1100 \mathrm{U}+0000$.

NOTE - The number of code positions is not necessarily the same as the number of simple letters. One code position can contain one, two or three simple letters.
c) If a syllable-initial part of a syllable is composed of three simple letters (<si1> <si2> <si3>), then that part is transformed into "<si1> <si2> <si3>". For example, U+1123 $\rightarrow \mathrm{U}+1107 \mathrm{U}+1109 \mathrm{U}+1103$; $\mathrm{U}+1107 \mathrm{U}+1109 \mathrm{U}+1103 \rightarrow \mathrm{U}+1107 \mathrm{U}+1109 \mathrm{U}+1103$. This operation does not actually change the content of the string.
d) Syllable-peak and syllable-final parts are transformed in a similar manner.
e) A syllable-initial filler character $\mathrm{U}+115 \mathrm{~F}$ is transformed into "U+115F U+0000 U+0000".
f) A syllable-peak filler character $U+1160$ is transformed into "U+1160 U+0000 U+0000".

## C.4.4 Step 3

A complete or incomplete syllable is transformed into nine simple letters.
a) If a complete syllable is composed of syllable-initial and syllable-peak letters (<si1> <si2> <si3> <sp1> <sp2> <sp3>), then the syllable is transformed into "<si1> <si2> <si3> <sp1> <sp2> <sp3> U+0000 $\mathrm{U}+0000 \mathrm{U}+0000$ ". For example, $\mathrm{U}+1100 \mathrm{U}+0000 \mathrm{U}+0000 \mathrm{U}+1161 \mathrm{U}+0000 \mathrm{U}+0000 \rightarrow \mathrm{U}+1100 \mathrm{U}+0000$ $U+0000 U+1161 U+0000 U+0000 U+0000 U+0000 U+0000$.
b) If a complete syllable is composed of syllable-initial, syllable-peak, and syllable-final letters (<si1> <si2> <si3> <sp1> <sp2> <sp3> <sf1> <sf2> <sf3>), then the syllable is remains unchanged. For example, $U+1100 \mathrm{U}+0000 \mathrm{U}+0000 \mathrm{U}+1161 \mathrm{U}+0000 \mathrm{U}+0000 \mathrm{U}+11 \mathrm{~A} 8 \mathrm{U}+0000 \mathrm{U}+0000$ remains unchanged.
c) If an incomplete syllable is composed of only a syllable-initial letter ( $<$ si1 $><$ si2 $><$ si3 $>\mathrm{U}+1160 \mathrm{U}+0000$ $\mathrm{U}+0000$ ), then the syllable is transformed into "<si1> <si2> <si3> U+1160 U+0000 U+0000 U+0000 $U+0000 U+0000$ ". For example, $U+1100 U+0000 U+0000 U+1160 U+0000 U+0000 \rightarrow U+1100 U+0000$ $U+0000 U+1160 U+0000 U+0000 U+0000 U+0000 U+0000$.
d) If an incomplete syllable is composed of only a syllable-peak letter ( $\mathrm{U}+115 \mathrm{~F} U+0000 \mathrm{U}+0000<$ sp1> <sp2> <sp3>), then the syllable is transformed into "U+FFFF U+0000 U+0000 <sp1> <sp2> <sp3> $U+0000 U+0000 U+0000{ }^{\prime}$. For example, $U+115 F U+0000 U+0000 U+1161 U+0000 U+0000 \rightarrow U+F F F F$ $\mathrm{U}+0000 \mathrm{U}+0000 \mathrm{U}+1161 \mathrm{U}+0000 \mathrm{U}+0000 \mathrm{U}+0000 \mathrm{U}+0000 \mathrm{U}+0000$.

## Committee Draft (CD)

e) If an incomplete syllable is composed of syllable-peak and syllable-final letters (U+115F U+0000 $\mathrm{U}+0000$ <sp1> <sp2> <sp3> <sf1> <sf2> <sf3>), then the syllable is transformed into "U+FFFF U+0000 U+0000 <sp1> <sp2> <sp3> <sf1> <sf2> <sf3>". For example, U+115F U+0000 U+0000 U+1161 $U+0000 U+0000 U+11 A 8 U+0000 U+0000$ Is transformed into "U+FFFF U+0000 U+0000 U+1161 $\mathrm{U}+0000 \mathrm{U}+0000 \mathrm{U}+11 \mathrm{~A} 8 \mathrm{U}+0000 \mathrm{U}+0000$ ".
f) If an incomplete syllable is composed of only a syllable-final letter (U+115F U+0000 U+0000 U+1160 $\mathrm{U}+0000 \mathrm{U}+0000$ <sf1> <sf2> <sf3>), then the syllable is transformed into "U+FFFF U+0000 U+0000 U+FFFF U+0000 U+0000 <sf1> <sf2> <sf3>". For example, U+115F U+0000 U+0000 U+1160 U+0000 $\mathrm{U}+0000 \mathrm{U}+118 \mathrm{~A} \mathrm{U}+0000 \mathrm{U}+0000 \rightarrow \mathrm{U}+\mathrm{FFFF} \mathrm{U}+0000 \mathrm{U}+0000 \mathrm{U}+F F F F \mathrm{U}+0000 \mathrm{U}+0000 \mathrm{U}+118 \mathrm{~A}$ U+0000 U+0000.

Now the pre-processing is done.

## C.4.5 Step 4

The transformed data is input to the algorithm implementing this document, to collate properly with a CTT modified to produce the desired collating order.

Steps 1 to 3 show how to properly pre-process Hangul data without considering efficiency. There could be more efficient pre-processing algorithms. As long as an algorithm implementing this document takes the output from such pre-processing algorithm and gives the same end results for collation, such alternative pre-processing algorithms can be used.

Instead of inputting the transformed Hangul data to a separate algorithm implementing this document, one could combine steps 1 to 4 into a single process which gives the same end results for collation and is more efficient. That issue does not concern pre-processing as such.

## Annex D <br> (informative) <br> Tutorial on solutions brought by this document to problems of lexical ordering

## D. 1 General

Why do existing standard character codes, with character-by-character comparisons, not give appropriate resulting ordering of strings? What needs to be done in order to get appropriate resulting orderings? This annex illustrates this with examples the Latin script.

## D. 2 Problems

a) Sorting, in any language using the Latin script, including English, using, for example, ISO/IEC 646 coding, does not follow traditional dictionary sequence, which is the minimum the average user needs.

For example: Ordering the list "august", "August", "container", "coop", "co-op", "Vice-president", "Vice versa" gives the following order, if ISO/IEC 646 coding is used and a simple sort following binary order is performed:

```
August
Vice versa
Vice-president
august
co-op
container
coop
```

This ordering is obviously incorrect.
b) Transforming uppercase to lowercase and removing special characters yields a sorted list acceptable to users, but also yields unpredictable results.

For example: Sorting the list "August", "august", "coop", "co-op" gives the following order:
August
august
coop
co-op
Sorting the same list with a different initial order, say, "august", "co-op", "August", "coop" may give a different order with this method:

```
august
August
co-op
coop
```

c) If accented characters are introduced using, for example, any ISO/IEC 8-bit character set, the same problems as encountered above are amplified but they share the same causes.
d) If character code point tables were reorganized to make all related characters contiguous, one might think that a simplified single-character sort would result, but this does not work either. Take upper and lowercase unaccented letters as an example. If code position 01 is assigned to "a", code position 02 assigned to "A", code position 03 to " b ", code position 04 to " B " and so on, a list sorted directly according to these rearranged values will yield the following:

| Sorted <br> List | Internal <br> Values |
| :--- | :--- |
|  |  |
| Aaaa | 01010101 |
| abbb | 01030303 |
| Aaaa | 02010101 |
| Ab.bb | 02030303 |

This is also predictable but remains obviously incorrect for any country with regard to cultural expectations.

## D. 3 Solution

The only solution to the above problems is to consider the initial data in multiple levels in a way that will respect traditional lexical order, and at the same time, ensure absolute predictability. For the Latin script, this can be achieved by comparing in four (or more) levels.
a) The first level renders the texts to be sorted case-insensitive and insensitive to diacritical marks, and to all special characters (which have no pre-established traditional order).

An example for English:
"résumé" ('curriculum vitae') becomes "resume" ('begin again'), without any accent.
An example for French:
"Vice-légation" becomes "vicelegation", with no accent, no uppercase and no hyphen.
An example for German:
"groß" becomes "gross", with the sharp-s being converted to double-s for the ordering.
In some languages, including Spanish and the Nordic languages, some extra letters are added to the 26 letters of the English, French, and German alphabets. The additional letters are not ordered according to the expectations in other languages. This demonstrates the need for adaptability.
b) The second level breaks ties on quasi-homographs, that is, strings that differ only because they have different diacritical marks.

In English, "resumé" and "résumé" are quasi-homographs. Traditional English lexical order requires that "resume" always comes before "résumé" (which sorting using only the first level would not guarantee). In this case, the tradition does not explicitly specify whether "resumé" should come before "résumé", though this would seem logical: most English and German dictionaries only state that unaccented words precede the accented words. However, German dictionaries generally employ the German standard DIN 5007, which states rules that are more precise.

Here, another characteristic is introduced. In French, because of the large number of multiple quasihomograph groups formed of more than two instances, the most important dictionaries follow the following rule: accents are generally not taken into account for sorting, but in case of homographic ties, the last difference in the word determines the correct order between two given words. A priority order is assigned to each type of accent. According to this, "coté" should be sorted after "côte" but before "côté". This is easy to implement with "backwards" tailoring. A number is assigned to each character of the data to be sorted, representing either a letter with an accent or a letter with no accent at all, but these numbers are prepended instead of being appended to the result being constructed. In other words, the resulting string is made starting from the last character of the original data and processing in a backwards direction.

For example, to obtain an order respecting this rule: "cote, "côte", "coté", "côté", numbers could be assigned indicating respectively "****", "** $\mathrm{C}^{* ", ~ " A * * * ", ~ " A * C * ", ~ w h e r e ~ " * " ~ m e a n s ~ n o ~ a c c e n t, ~ " A " ~ m e a n s ~ a c u t e ~}$ accent, "C" circumflex accent. This scheme is sufficient to break the tie correctly at this second level.
c) The third level breaks ties for quasi-homographs that differ only because uppercase and lowercase characters are used.

This time, the tradition is well established in German dictionaries, where lowercase always precedes uppercase in homographs, while the tradition is not well established in French dictionaries, which generally use only accented capital letters for common word entries. In known French dictionaries where uppercase and lowercase letters are mixed, the capitals generally come first, though this is not an established and stated rule, because there are numerous exceptions. English has no monolithic practice for this, a bit like French. Therefore, for a Common Template it is advisable to use the well-established German tradition, if one wants to group the largest possible number of languages together without affecting others. Note that in Denmark, uppercase is specified to precede lowercase, a different but well-
established rule. This is a second fact that demonstrates the need for adaptability in the model used in this document.

For example: to have the following order: "august", "August", numbers could be assigned indicating respectively "LLLLLL", "ULLLLL", where "L" means lowercase and "U" uppercase.
d) The fourth level breaks the final tie that, in general, does not correspond to any strong tradition, namely, the tie between quasi-homographs differing only because they contain special characters.

Breaking this tie is essential to ensure the predictability of ordering as well as enabling the ordering of strings composed only of special characters. Since the traces of special characters were removed from the original data to form the three first levels, simply putting them sequentially in the fourth order of decomposition would mean that their position would be lost. These positions are needed to resolve remaining ties, so the original positions of these special characters shall be retained somehow. For example, two quasi-homographs could each contain a common special character in different positions and thus be strictly different (example: " $a b^{*} c d$ " is different from "a*bcd" despite they share one and only one common special character).

For example, to obtain the following order: "coop", "co-op", "coop-", numbers could be assigned respectively according to the following pattern: "", "3-", and "5-"; where "3-" means a hyphen in (relative) position 3 of the original string. "5-" means a hyphen in (relative) position 5, and so on.

These four levels can be composed to a four-level key, concatenating the subkeys from the most significant to the least significant, putting the lowest value possible as a delimiter between each subkey. The ordering result can then be obtained through the numeric order of the keys.

If the assignment of weight numbers is done properly, one can eliminate some of the delimiter weights. To eliminate the level delimiter between the first and second level subkeys, choose the numbers for the second level weights be less than numbers for the first level weights. To eliminate the level delimiter between the second and third level subkeys, choose the numbers for the third level weights be less than numbers for the second level weights.

Subkey reduction techniques have been designed to considerably shorten space requirements. As no implementation is required to use specific numbers for weights and reduction is not required, this issue is outside the scope of this document. Nevertheless, it is interesting to note that implementation can be optimized. This has been improved over time and is easy to accomplish, some methods being more efficient than others. This method for string collation was described with tables in Règles du classement alphabétique en langue française et procédure informatisée pour le tri, Alain LaBonté, Ministère des Communications du Québec, 1988-08-19, ISBN 2-550-19046-7. A public-domain subkey reduction technique is described (with several examples) in Technique de réduction - Tris informatiques à quatre clés, Alain LaBonté, Ministère des Communications du Québec, 1989-06, ISBN 2-550-19965-0. See also the paper by Rolf Gavare, Alphabetic ordering in a lexicological perspective, Studies in Computer-Aided Lexicology, 1988, pp. 63-102, which also describes a multi-level string collation technique, with subkey compression.

## D. 4 Tailoring

For a number of languages, the Common Template Table will need to be adapted. Adaptation may be needed both in the table values for the four levels of subkeys, which can require redefining weightings for characters or introducing multi-character collating elements into the table, as well as changes in the potential context analysis processing necessary to achieve culturally correct results for users of these languages.

To illustrate this, without discussing context analysis which is not necessary in what follows, examples of dictionary sequences are given here for two languages whose expected ordering rules are not covered the Common Template Table.

For traditional Spanish, where "ch" is greater than "cu" and "ña" is greater than "no":
cuneo < cúneo < chapeo < nodo < ñaco

Comparative French/English/German sort of the same strings:
chapeo < cuneo < cúneo < ñaco < nodo

For Danish, where "a" is less than "c", "cz" is less than "cæ" and "cø", and "aa" is equivalent to "å", which is greater than "z", even in cases where it is pronounced differently:
Alzheimer < czar < cæsium < cølibat < Aachen < Aalborg < Århus

Comparative French/English/German sort of the same strings:
Aachen < Aalborg < Alzheimer < Århus < cæsium < cølibat < czar
Similarly, Japanese will need tailoring in order to handle the length mark properly. For many other orthographies, some degree of tailoring will be necessary.

## Annex E <br> (informative) <br> Searching and fuzzy matches

At the fundamental level of comparison of a string with a target corpus, simple textual information retrieval widely uses, implicitly or not, the same concepts and the same conventions as string collation.

It is indeed often useful to be able to search without regard to case, diacritical marks or even special characters ("ignorable" characters). Thus, as a case in point using French, a search for keyword "contremaitre" could equally retrieve as legitimate targets the words "contremaître" or "contre-maître" (the latter being considered an old spelling of the same word), or "contremaitre" (without circumflex accent on the i, a new spelling now admitted in this particular unambiguous case). It could as well retrieve "CONTREMAITRE", as some uses of the language do not put accents on capitals and thus may very well be found in a text corpus.

To ensure adequacy of a match - fuzzy or exact - with user expectations, it is appropriate to consider that the comparison functions used be based on the same comparison method as the one used for sorting. However, the concepts of "fuzziness" used in information retrieval extend far beyond the simple concepts of case-, accent- or special-character-independence. There are particular search functions on prefixes, taking into account word morphology (word search based on their roots), phonetics, or even equivalences in a foreign language. Complex fuzzy search - a requirement that goes far beyond the scope of this document - could, for example, regard as equivalent two strings according to their broad phonetic value, such as "cinq sens" and "Saint-Saëns" in French (pronounced exactly the same). Similarly, some could want to consider as equivalent inflected grammatical forms such as "œil" and "yeux" in French (the latter simply being the plural of the former word). An example in English would be the words "man" and "men".

Given the wide variety of fuzziness concepts, we will only discuss here the simple fuzziness cases based on the different levels of weighting used in this document.

If one follows the scope of this document, the search operation should use the same comparison method, separating base characters, diacritical marks, case and other characters (special characters, typographical marks and symbols). However, some levels may be omitted in the comparison, depending on the level of precision necessary to consider a match.

This means that, as cases in point:

- A search that is independent of diacritical marks should consider as equivalent (marked "<>" in examples) all strings that only differ at level 2 in the comparison process.

EXAMPLE contremaître <> contremaitre

- A search that is independent of case should consider as equivalent all strings that only differ at level 3 in the comparison process.

EXAMPLE contremaître <> CONTREMAÎTRE

- A search that is independent of special ("ignorable") characters should consider as equivalent all strings that only differ at level 4 in the comparison process.

EXAMPLE contremaître <> contre-maître

- A search that intends to retrieve all loosely-similar variants should consider as equivalent all words which only match at level 1.

EXAMPLE contremaître <> contre-maitre <> contremaitre <> CONTREMAÎTRE <> Contre-maître [etc.]
The latter case is to be considered typical in simple searches and should be the preferred way in absence of specialized needs.

It is recommended that the user be made aware of the search parameters using appropriate user interface elements.

NOTE For discussions about this subject, see the following:

- Unicode Technical Standard \#10 Unicode Collation Algorithm — See Clause 2.
- Standard sur le tri alphabétique et la recherche de chaînes de caractères (SGQRI 004, Québec Government), in particular clauses 4 and 6 (publication in French only) - See [13].
